where

\[ K_m = \frac{\partial \ln \phi_m}{\partial \ln P_m} \]  
\[ K_s = \frac{\partial \ln \phi_s}{\partial \ln P_s} \]  

In eqs 3-5, \( P \) is the pressure, \( x_m \) is the equilibrium mole fraction of the mobile-phase fluid in the stationary phase, \( \phi_m \) is the infinite-dilution fugacity coefficient of the solute in the stationary phase, \( \partial \ln \phi_m / \partial P_m \) is the isothermal compressibility of the stationary phase, and \( V_s \) and \( V_m \) are the volumes of the stationary and the mobile phases in the column, respectively. The derivation and discussion of eqs 3-5 may be found elsewhere.20 It should only be emphasized here that eqs 3 is a local value at some particular position within the column rather than the experimentally observed, average value over the pressure drop across the column.

In a similar way, the derivative with respect to the molar density of the mobile phase may be written as

\[ \frac{\partial \ln k_i / \partial n_m}{\partial \ln P_m} = \frac{Q_m}{m} + \frac{Q_s}{\rho_m - \rho_m \beta_m} + K_m / (\rho_m \beta_m) \]  

The quantities \( \partial \ln k_i / \partial n_m \) and \( \beta_m \) in eq 4 combine in such a way that straightforward relationships result between \( K_m / (\rho_m \beta_m) \) and the molecular quantities of eqs 1 and 2. After simple rearrangements, one obtains

\[ \int c_T(r) \, dr = -K_m / (N_A \rho_m \beta_m) = -Q_m / N_A \]  
\[ \chi = -RT \rho_m K_m = -RT \rho_m^2 \beta_m Q_m \]

13^C \text{NMR Study of the C60 Cluster in the Solid State: Molecular Motion and Carbon Chemical Shift Anisotropy}
\end{align*} \]

IBM Research Division, Almaden Research Center, San Jose, California 95120-6099

(Received: November 12, 1990)

\[ \begin{align*}
\text{13}^C \text{NMR spectra of solid buckminsterfullerene, the soccerball-like cluster of 60 carbon atoms, have been obtained at temperatures down to 77 K. The ambient spectrum shows rapid isotropic rotational motion. The motion is sufficiently slow at 72 K that a measurement of the chemical shift tensor of the carbon nucleus can be made. The tensor components (220, 186, 40 ppm) have values that are typical for an aromatic carbon. Spectra at intermediate temperatures suggest the possibility of either growth of a low-temperature phase in which C60 rotation is inhibited or a distribution of rotational correlation times.}
\end{align*} \]

Raman spectra of C60 strongly support the soccerball geometry for this molecule, and solution NMR spectra have shown that the molecule has icosahedral point group symmetry. The pseudospherical symmetry of this molecule suggests potential for facile isotropic motion in the solid state, and solid-state NMR spectroscopy is uniquely suited as a probe of this kind of molecular dynamics.

The sample was prepared by toluene extraction of soot produced by arc heating graphite in 100 Torr of He.3 The dried powder consists mainly of C60 and C70 in a ratio of 10:1 and also shows a strong, sharp (1.5-G width) EPR signal at g \approx 2.

\[ \text{13}^C \text{NMR spectra of approximately 1 g of sample have been obtained at 1.4 T (15 MHz). Figure 1 shows spectra at several tempera-} \]

The chemical shift anisotropy is expected to extend over \( \sim 200 \) ppm, \( 3 \text{ kHz at 1.4 T} \), the relevant time scale is \( \sim 10^{-4} \) s. Measurements of the \(^{13}\text{C}\) spin–lattice relaxation time at 7.04 T show a \( T_1 \) minimum at 233 K, indicating that the correlation time for molecular motion at this temperature is \( \sim 10^{-9} \) s. Thus, \( \text{C}_6\text{O}_6 \) molecules must be rotating at rates \( >10^9 \) s\(^{-1} \) at ambient temperatures. The spectrum at 123 K shows that a broad skirt has developed at the base of the main resonance at 143 ppm. At 100 K, the spectrum is predominantly a powder pattern characteristic of a chemical shift anisotropy with minor intensity in the narrow peak at 143 ppm. At 77 K the same powder pattern is observed with little evidence of the narrow line at 143 ppm. A fit of the powder pattern yields an asymmetric chemical shift tensor as expected for a carbon in the \( \text{C}_6\text{O}_6 \) cluster. The components of the tensor, 220, 186, and 40 ppm, confirm the aromatic character of the carbons in \( \text{C}_6\text{O}_6 \).

As shown in Figure 1, as the temperature is lowered, the intensity of the narrow peak due to rapidly rotating \( \text{C}_6\text{O}_6 \) decreases while a spectrum reflecting static molecules builds up. This evolution may be explained either by growth, as the temperature is lowered, of a phase in which cluster rotation is inhibited or by a distribution of rotational correlation times and a concomitant distribution of motional barriers.

In conclusion, we report results that show that the \( \text{C}_6\text{O}_6 \) cluster rotates rapidly and isotropically in the solid state at ambient temperatures and that by lowering the temperature this motion can be slowed to the extent that the carbon chemical shift anisotropy can be measured. The resulting chemical shift tensor confirms the aromatic nature of the carbons in \( \text{C}_6\text{O}_6 \). The \(^{13}\text{C}\) spectra also suggest either growth of a new phase as the temperature is lowered or a distribution of motional dynamics, possibly due to sample heterogeneity. Experiments that may permit us to distinguish between these two possibilities are in progress. A careful study of the temperature dependence of the \(^{13}\text{C}\) NMR line shape to probe the details of the motional dynamics is also planned. A further implication of these results is that it may be necessary to cool \( \text{C}_6\text{O}_6 \) to low temperatures to explore its structure by diffraction methods or to image individual atoms by using STM.

Acknowledgment. We thank R. D. Kendrick and G. May for assistance with the NMR experiments and H. E. Hunziker for stimulating discussions.

Figure 1. \(^{13}\text{C}\) NMR spectra of solid \( \text{C}_6\text{O}_6 \) obtained at ambient and 123, 100, and 77 K. Recycle times (seconds/number of scans at each temperature) are as follows: ambient, 8/3108; 123 K, 1/1520; 100 K, 8/14400; 77 K, 8/7342.
